DECLARATION UNDER 37 C.F.R. § 1.132

Assistant Commissioner for Patents Alexandria, VA 22313-1450

Sir:

I, Yumiko TAKESHITA of 11-46, Senzui 3-chome, Asaka-shi, Saitama, Japan, hereby declare and state that I received a Bachelor degree of Chemical and Biological Sciences from Japan Woman's University on March 1989 and that I have been employed as a worker in research by Fuji Photo Film Co. Ltd. since April 1989. .

I declare that I am at present doing research work on nucleic acid extraction and detection in Life Science Research Laboratory of said company.

I am familiar with the subject matter disclosed by the application.

The following experimentation was conducted by me, or under my supervision and control.

Preparation of Cellulose Microcapsule

A cellulose microcapaule was prepared in the same manner as in Example 12 of U.S. Patent No. 4,118,336 (Morishita) except for reducing a scale to 1/4. Specially, 10 g of bentonite powder was added to a solution of 2.5 g of cellulose triacetate in 50 ml of methylene chloride and was dispersed. The resulting dispersion was dispersed with propeller stirring to the form of fine droplets into 200 ml of an aqueous solution containing 1 g of sodium laurylbenzene sulfonate dissolved herein. After the methylene chloride was removed by an evaporator to form microcapsules, the microcapsules formed was tried to be filtered, but a clogging of the filter occurred completely. Due to the clogging, various filters such as a glass filter and paper filter were tried, but even in all of the filters, a clogging occurred. Thus, a precipitate was separated, and the remaining was freeze-dried. To the precipitate and the freeze-dried product were added 30 ml of water to be washed three times (a centrifugation with 1500 rpm for 10 minutes and removal of the supermatant was performed three times) to obtain microcapsules encapsulated with cellulose triacetate containing bentonite powder.

Subsequently, 10 g of the microcapsules were swelled for 30 minutes in 6 ml of a mixture of ethanol and water (1:1), and then the supernatant was removed by a centrifugation. The pellet was charged into 6 ml of 0.5 N sodium hydroxide and saponified with stirring at 50°C for 30 minutes. Thereafter, the microcapsules was washed with water three times and then cellulose microcapsule was obtained.

The separation and purification of a plasmid DNA from a recombinant bacterium was performed by using the cellulose microcapsule obtained above.

Docket No.: 0649-0963P

Preparation of Solution containing a plasmid DNA

A frozen recombinant bacterium containing a plasmid: pBlueScript II/GAPDH/DH5α was thawed at a room temperature, and then the thawed recombinant bacterium was subjected to a tapping of ten times. To the tapped material was added 100 μl of RDP dispersion (50mM TrisHCl and 10mM EDTA: pH 8.1) containing 3 μl of EDP-A solution (0.3 mg/ml of RNase A and 0.27 mM of sodium acetate) and 1 μl of EDP-B solution (0.01 mg/ml of RNase T1 and 32 mM of anumonium sulfate). After the solution was vortexed at a maximum speed for 15 seconds, to the vortexed solution was added 100 gH of ADP solution (0.2N sodium hydroxide was slowly performed five times. To the obtained solution was added 140 gH of NDP solution (3M NDP, an inversion mixture was slowly potassium acetate and 13.6% acetic acid: pH 5.5). Immediately after the addition of NDP, an inversion mixture was slowly performed five times. The obtained solution was then contrifuged at 18,000g for 10 minutes at room temperature, and then the supernatant was isolated as a solution containing a plasmid DNA (approximately 330 μl).

Isolation of Plasmid DNA

(1) To 1.7 ml of tube, 70 mg of the cellulose microcapsule obtained above, 320 µl of LDP to solution (31.3 mM Bis-Tris and 7.1% Tween 20 in 68.5% of ethanol: pH 6.0) and the obtained solution solution containing a plasmid DNA (approximately 330 µl) were added. The obtained solution was subjected to vortexing at a maximum speed for 30 minutes, and then was subjected to a clogging, and the plasmid DNA was not able to be isolated.

Application No. 10/621,715

Docket No.: 0649-0963P

On the contrary, the method of the present invention can isolate the plasmid DNA by the above-mentioned operation.

(2) Instead to the above operation, the whole solution containing a plasmid DNA (approximately 330 μl) after several-time pipetting was added to a tube containing 70 mg of the cellulose microcapsule obtained above. The obtained solution was subjected to vortexing for one minute and centrifuging at 1,000g for one minute, and the supernatant was removed. To the pellet, 750 ph of a washing solution (10.8 mM TrisHCl in 80% of ethanol: pH 7.8) was added.

The obtained solution was subjected to vortexing for one minute and centrifuging at 1,000g for one minute, and the supernatant was removed. To the pellet, 750 μl of the washing solution was added. The obtained solution was subjected to vortexing for one minute and centrifuging at 1,000g for one minute, and the supernatant was removed. To the pellet, 50 ph of a recovering (2.5) solution (10 mM TrisHCl: pH (3.5) was added, and then the obtained solution was subjected to vortexing for one minute and centrifuging at 1,000g for one minute to obtain the plasmid.

Although a plasmid DNA can be isolated by many further operations in Morishita, the many further operations are an extremely troublesome. Accordingly, from the above result, it can be recognized that the method of the present invention at least has an excellent separation performance.
